

## Overview

### Useful For

An adjunct in the evaluation of menstrual irregularities

Evaluating patients with suspected hypogonadism

Predicting ovulation

Evaluating infertility

Diagnosing pituitary disorders

### Method Name

Electrochemiluminescence Immunoassay

### NY State Available

No

## Specimen

### Specimen Type

Serum

### Specimen Required

**Collection Container/Tube:**

**Preferred:** Serum gel

**Acceptable:** Red top

**Submission Container/Tube:** Plastic vial

**Specimen Volume:** 0.6 mL

**Collection Instructions:** Centrifuge and aliquot serum into a plastic vial within 2 hours of collection.

### Forms

If not ordering electronically, complete, print, and send an [Oncology Test Request](#) (T729) with the specimen.

### Specimen Minimum Volume

0.5 mL

### Reject Due To

|                 |        |
|-----------------|--------|
| Gross hemolysis | Reject |
|-----------------|--------|

|               |        |
|---------------|--------|
| Gross lipemia | OK     |
| Gross icterus | Reject |

## Specimen Stability Information

| Specimen Type | Temperature              | Time     | Special Container |
|---------------|--------------------------|----------|-------------------|
| Serum         | Refrigerated (preferred) | 7 days   |                   |
|               | Frozen                   | 180 days |                   |
|               | Ambient                  | 24 hours |                   |

## Clinical & Interpretive

### Clinical Information

Luteinizing hormone (LH) is a glycoprotein hormone consisting of 2 noncovalently bound subunits (alpha and beta). Gonadotropin-releasing hormone from the hypothalamus controls the secretion of the gonadotropins, follicle-stimulating hormone (FSH) and LH, from the anterior pituitary.

The menstrual cycle is divided by a midcycle surge of both FSH and LH into a follicular phase and a luteal phase.

FSH appears to control gametogenesis in both male and female individuals.

### Reference Values

#### Males

<12 months: < or =3.3 IU/L

12 months-5 years: < or =1.9 IU/L

>5 years-10 years: < or =2.3 IU/L

>10 years-15 years: 0.6-6.9 IU/L

>15 years-18 years: 0.7-9.6 IU/L

>18 years: 1.2-15.8 IU/L

#### TANNER STAGES\*

Stage I: <1.5 IU/L

Stage II: <3.0 IU/L

Stage III: 0.4-6.2 IU/L

Stage IV: 0.6-5.1 IU/L

Stage V: 0.8-7.2 IU/L

\*Puberty onset occurs for boys at a median age of 11.5 (+/- 2) years. For boys, there is no proven relationship between puberty onset and body weight or ethnic origin. Progression through Tanner stages is variable. Tanner stage V (adult) should be reached by age 18.

#### Females

<12 months: 1.2-12.5 IU/L

12 months-10 years: 0.5-6.0 IU/L

>10 years-15 years: 0.9-8.9 IU/L

>15 years-18 years: 0.7-9.6 IU/L

Premenopausal:

Follicular: 2.9-14.6 IU/L

Midcycle: 4.7-23.2 IU/L

Luteal: 1.4-8.9 IU/L

Postmenopausal: 16.0-157.0 IU/L

#### TANNER STAGES\*

Stage I: 0.6-4.1 IU/L

Stage II: 0.3-5.8 IU/L

Stage III: 0.1-7.2 IU/L

Stage IV: 0.3-7.0 IU/L

Stage V: 0.4-8.6 IU/L

\*Puberty onset (transition from Tanner stage I to Tanner stage II) occurs for girls at a median age of 10.5 (+/- 2) years. There is evidence that it may occur up to 1 year earlier in obese girls and in African American girls. Progression through Tanner stages is variable. Tanner stage V (adult) should be reached by age 18.

#### Interpretation

In both male and female patients, primary hypogonadism results in an elevation of basal follicle-stimulating hormone (FSH) and luteinizing hormone (LH) levels.

FSH and LH are generally elevated in:

- Primary gonadal failure
- Complete testicular feminization syndrome
- Precocious puberty (either idiopathic or secondary to a central nervous system lesion)
- Menopause (postmenopausal FSH levels are generally >40 IU/L)
- Primary ovarian hypofunction in female patients
- Primary hypogonadism in male patients

Normal or decreased FSH in:

- Polycystic ovary disease in female patients

FSH and LH are both decreased in failure of the pituitary or hypothalamus.

#### Cautions

Serum biotin concentrations up to 1200 ng/mL do not interfere with this assay. Concentrations up to 1200 ng/mL may be present in specimens collected from patients taking extremely high doses of biotin up to 300 mg per day.(1) In a study among 54 healthy volunteers, supplementation with 20 mg/day biotin resulted in a maximum serum biotin concentration of 355 ng/mL 1 hour post-dose.(2)

No clinically significant cross-reactivity has been demonstrated with thyrotropin (formerly thyroid-stimulating hormone), luteinizing hormone, human chorionic gonadotropin, prolactin, or growth hormone.

Some patients who have been exposed to animal antigens, either in the environment or as part of treatment or imaging procedures, may have circulating anti-animal antibodies present. These antibodies may interfere with the assay reagents to produce unreliable results.

**Performance****Method Description**

The Roche follicle-stimulating hormone (FSH) method employs monoclonal antibodies specifically directed against FSH. A biotinylated monoclonal antibody and a second monoclonal antibody labeled with a ruthenium complex react to form a sandwich complex. After the addition of streptavidin-coated microparticles, the complex becomes bound to the solid phase via interaction of biotin and streptavidin. The reaction mixture is aspirated into the measuring cell where the microparticles are magnetically captured onto the surface of the electrode. Application of a voltage to the electrode then induces chemiluminescent emission, which is measured by a photomultiplier. (Package insert: FSH. Roche Diagnostics; 10/2021)

**PDF Report**

No

**Day(s) Performed**

Monday through Friday, Sunday

**Report Available**

Same day/1 to 2 days

**Specimen Retention Time**

14 days

**Performing Laboratory Location**

Jacksonville
